

# THIN TYPE BALL GRID ARRAY PACKAGE

## FIELD OF THE INVENTION

The present invention is relating to a ball grid array package, particularly to a thin type ball grid array package with a composite substrate including a dummy die.

## BACKGROUND OF THE INVENTION

According to a conventional thin type ball grid array package (thin type BGA package), an integrated circuit chip is accommodated inside the cavity of a BGA package substrate for reducing the total height of the package

A thin type BGA package had been disclosed in U.S. Patent No. 6,486,537 entitled "semiconductor package with warpage resistant substrate". The thin type BGA package comprises a BGA package substrate with a through hole and a chip positioned in the through hole by a hardened encapsulate material. During molding process, back surface of the chip is attached to a temporary adhesive inside a mold and the back surface of the chip is exposed to the encapsulating material. Since only the back surface of the chip is used for thermal dissipation, the thin type BGA package not only has poor thermal dissipation, but also cannot supply enough protection to the chip due to the exposed back surface of the chip, resulting in easily damaging the chip and poor reliability.

## SUMMARY

A primary objective of the present invention is to provide a thin type BGA package having a composite substrate. A dummy die is attached to a wiring board with an opening to form a composite substrate with a chip cavity. The dummy die covers the opening for mounting an integrated circuit chip in the chip cavity. The wiring board has a step formed in the opening for electrically connecting the chip. The chip is attached to the dummy die of the composite substrate so that the thin type BGA package has a larger thermal dissipating surface and a better protection for the chip. Moreover, CTEs (coefficient of thermal expansion) of the chip and the dummy die are the same, so the interface between the chip and the dummy die will not have residual thermal stress,

1 therefore, delamination can be eliminated.

2 A secondary objective of the present invention is to provide a thin type BGA  
3 package. A dummy die is attached to a wiring board with an opening to form a  
4 composite substrate. The dummy die covers the opening so as to form a chip cavity for  
5 accommodating an integrated circuit chip which has the advantage to achieve a smaller  
6 total package height.

7 According to the thin type BGA package of the present invention, the package  
8 comprises a composite substrate, an integrated circuit chip, a package body and a  
9 plurality of solder balls. The composite substrate includes a wiring board and a dummy  
10 die. The wiring board has an upper surface, a lower surface and an opening. Ball pads  
11 are formed on the upper surface or the lower surface of the wiring board. A step with a  
12 plurality of connecting pads is formed in the opening. The connecting pads on the step  
13 are electrically connected with the chip by bonding wires to reduce the loop height. The  
14 dummy die is attached to the lower surface of the wiring board and covers the opening to  
15 form a chip cavity of the thin type BGA package which has the advantage to form the  
16 package body by dispensing method. The back surface of chip is attached to the dummy  
17 chip inside the chip cavity. A larger thermal dissipating surface is created on the  
18 exposed surface of the dummy chip. Moreover, there is no thermal stress between the  
19 interface of the chip and the dummy die due to the perfect matching of CTEs (coefficient  
20 of thermal expansion), so that the possibility of delamination at the interface can be  
21 effectively reduced. Therefore, excellent thermal dissipation, excellent protection of the  
22 die and excellent stress releasing of the chip can be achieved.

#### 23 DESCRIPTION OF THE DRAWINGS

24 Fig.1 is a cross-sectional view illustrating a thin type BGA package of the present  
25 invention.

26 Fig.2A to Fig.2D is cross-sectional views illustrating manufacturing process of a  
27 thin type BGA package of the present invention.

1        Fig.3 is a cross-sectional view illustrating another thin type BGA package of the  
2 present invention.

### 3                    DETAILED DESCRIPTION OF THE PRESENT INVENTION

4        Referring to the drawings attached, the present invention will be described by means  
5 of the embodiment below.

6        According to a first embodiment of the present invention showed in Fig.1, a thin  
7 type BGA package 1 comprises a composite substrate 10, an integrated circuit chip 30, a  
8 package body 40 and a plurality of solder balls 50. The composite substrate 10 is  
9 consisted of a wiring board 11 with an opening 113, and a dummy die 12.

10        As shown FIG.1 and 2A, the wiring board 11 is a printed circuit board (PCB) made  
11 of glass fiber reinforced resin, such as FR-4, FR-5, BT resin, etc. The wiring board 11  
12 has multiple layers of metal traces, preferably it is made by a build-up processes. The  
13 wiring board 11 has an upper surface 111, a lower surface 112 and an opening 113  
14 passing through the upper surface 111 and the lower surface 112. The opening 113 is  
15 larger than the integrated circuit chip 30 in dimension for accommodating the integrated  
16 circuit chip 30. In the embodiment the wiring board 11 has a step 114 in the opening  
17 113. There is a plurality of connecting pads 115 formed on the step 114 between the  
18 upper surface 111 and the lower surface 112 for the connection of bonding wires.  
19 Furthermore, a plurality of ball pads 116 for the placement of solder balls 50 are formed  
20 on the lower surface 112 and electrically connected with the connecting pads 115 through  
21 the layers of traces. Alternatively the ball pads 116 may be formed on the upper surface  
22 111. The dummy die 12 is attached to the lower surface 112 of the wiring board 11 by a  
23 thermosetting compound 122, such as epoxy compound, and covers the opening 113.  
24 The dummy die 12 is larger than the opening 113 but is smaller than the wiring board 11  
25 in dimension. The dummy die 12 has a first surface 123 and an opposing second  
26 surface 124. The first surface 123 includes a central region 125 and a peripheral region  
27 126 surrounding the central region 125. The peripheral region 126 of the dummy die 12

1 is attached to the lower surface 112 of the wiring board 11 without covering the ball  
2 pads 116. The central region 125 is aligned to the opening 113. Thus a cavity is  
3 formed from the opening 113 and the dummy die 12 to accommodate an integrated  
4 circuit chip 30. The dummy die 12 may also be utilized to avoid contaminating the ball  
5 pads 116 during the formation of the package body 50. Further, the thickness of the  
6 dummy die 12 is smaller than the diameter of solder balls 50. Usually the dummy die  
7 12 can be a bare silicon chip without any active electrical elements or a discarded chip  
8 (also call an ink die). In this embodiment, the dummy die 12 does not have electrically  
9 connection with the wiring board 11. Preferably, a metal film 121 of copper or gold is  
10 formed on the exposed second surface 124 of the dummy die 12 by sputtering technique  
11 to improve thermal dissipation.

12 The integrated circuit chip 30 has an active surface 31 and a back surface 32  
13 corresponding to the active surface 31. A plurality of bonding pads 33 are formed on  
14 the active surface 31. The integrated circuit chip 30 is disposed inside the cavity of the  
15 composite substrate 10. The back surface 32 of the integrated circuit chip 30 is attached  
16 to the central region 125 of the dummy die 12 by adhesive 34 or tape. Because both the  
17 integrated circuit chip 30 and the dummy die 12 have the same coefficient of thermal  
18 expansion, there is no residual thermal stress at the interface between the integrated  
19 circuit chip 30 and the dummy die 12, which is much better than conventional BGA  
20 package which a chip is directly attached to the cavity of a substrate. A plurality of  
21 bonding wires 20 electrically connect the bonding pads 33 of the integrated circuit chip  
22 30 with the corresponding connecting pads 115 of the wiring board 11. The connecting  
23 pads 115 are formed at the step 114 so that the loop height of the bonding wires 20 are  
24 greatly reduced, preferably is lower than the upper surface 111 of the wiring board 11.

25 The package body 40 is formed in the chip cavity of the composite substrate 10 to  
26 seal the chip 30 and the bonding wires 20, which is located in the opening 113 of the  
27 wiring board 11. Preferably the package body 40 is a dispensing material. Since the

1 dummy die 12 covers the lower end of the opening 113 at the lower surface 112, the ball  
2 pads 116 can be not contaminated even without using special tape or molding tool during  
3 forming the package body 40. Preferably, a thermosetting liquid compound is filled into  
4 the opening 113 by dispensing then cured to form the package body 40, and the entire  
5 thin type BGA package 1 can be as thin as possible. The solder balls 50 are mounted on  
6 the ball pads 116 of the wiring board 11. In general, the solder balls 50 are lead-tin  
7 alloy. .

8 Therefore, the present invention mentioned above is to provide a thinner BGA  
9 package. The dummy die 12 is able to protect the back surface 32 of the integrated  
10 circuit chip 30, and to form the package body 40 without contaminating the ball pads 116  
11 of the wiring board 11. Moreover, the dummy die 12 may greatly increase the thermal  
12 dissipating surface of the integrated circuit chip 30 for enhancing thermal dissipation of  
13 the thin type BGA package 1.

14 A manufacturing method of the thin type BGA package 1 of the present invention  
15 will be described as follows. At first referring to Fig.2A, a wiring board 11 is provided.  
16 During the assembly processes, a plurality of the wiring boards 11 are formed on a large  
17 strip or matrix of a printed circuit board. Each wiring board 11 has the upper surface  
18 111, the lower surface 112 and the opening 113. The step 114 is formed in the opening  
19 113, and has a plurality of connecting pads 115. As shown in Fig.2B, a plurality of  
20 dummy dies 12 that are aligned with each opening 113 respectively and are attached to  
21 the lower surface 112 of the wiring board 11 by thermosetting compound 122 without  
22 covering the ball pads 116. A composite substrate 10 with a chip cavity for thin type  
23 BGA is formed. It is better that a metal film 121 is formed on the exposed second  
24 surface 124 of each dummy die 12 by sputtering method. Referring to Fig. 2C, a  
25 plurality of integrated circuit chips 30 are attached to the dummy dies 12. The back  
26 surface 32 is bonded with the central region 125 of the first surface 123 of the dummy die  
27 12 by adhesive 34. Then a plurality of bonding wires 20 electrically connect the

1 bonding pads 33 of the integrated circuit chips 30 with the connecting pads 115 of the  
2 wiring boards 11. Referring to Fig.2D, a package body 40 is formed in the chip cavity  
3 that is defined by the opening 113 and the dummy die 12, by liquid dispensing and curing  
4 processes. Finally, a plurality of solder balls 50 are mounted on the ball pads 116 on the  
5 lower surface 112 of the wiring board 11 to manufacture the thin type BGA package.

6 Referring to Fig.3, another thin type BGA package is disclosed according to a  
7 second embodiment of the present invention. The thin type BGA package mainly  
8 comprises a wiring board 11, a dummy die 12, bonding wires 20, an integrated circuit  
9 chip 30, a package body 40 and solder balls 50, that as same as those of thin type BGA  
10 package 1 will be indicated by the same figure number. The integrated circuit chip 30 is  
11 disposed in the chip cavity that is defined by the opening 113 of the wiring board 11 and  
12 the dummy die 12, and is sealed by the package body 40. A plurality of ball pads 116  
13 are formed on the lower surface 112 of the wiring board 11 for placing solder balls 50.  
14 A plurality of ball-stacking pads 117 are formed on the upper surface 111 of the wiring  
15 board 11 and are electrically connected with the corresponding ball pads 116. Solder  
16 balls 50 of an upper thin type BGA package are bonded to the ball-stacking pads 117 of  
17 the lower thin type BGA package, so that a plurality of thin type BGA packages can be  
18 stacked vertically. The thin type BGA package has a flat top surface with a smaller total  
19 package height so that more thin type BGA packages can be stacked together in a limited  
20 space without damaging the chips in the thin type BGA package.

21 The above description of embodiments of this invention is intended to be illustrated  
22 and not limiting. Other embodiments of this invention will be obvious to those skilled  
23 in the art in view of the above disclosure.
